Mary Kapella

This thesis is dedicated to my parents, Mansoorali and Rozina Mithani: for teaching me to trust in God, for providing me with the best available opportunities beyond their means, for supporting me through every step of my journey and for inspiring me always to aim higher.

ACKNOWLEDGEMENTS

“No honour is like knowledge. No belief is like modesty and patience, no attainment is like humility, no power is like forbearance, and no support is more reliable than consultation.”—Hazrat Ali ibn Abi Talib

First and foremost, I would like to acknowledge the National Institutes of Health (NIH)-National Institutes of Nursing Research Graduate Partnership Program and the University of Illinois at Chicago College of Nursing for establishing a partnership to support my dissertation research.

I want to acknowledge my dissertation chair, mentor, and advisor, Dr. Anne Fink. Thank you for your constant support and dedication since the first day of my Ph.D. program. She prioritized investing in me as an individual which has enabled me to succeed in diverse environments.

Dr. Jessica Gill, thank you for taking me into your lab during my first summer research experience at the NIH. Little did we know at the time that I would come back to the NIH to complete my dissertation under your mentorship. I am beyond grateful for your guidance and always supporting my research dreams. I am constantly in awe of your dedication and work ethic and I aspire to be a researcher and leader like you. It has been my greatest honor to work closely with you and I am excited to see where our research takes us in the future. I would also like to acknowledge our collaborator, Dr. Philip Gehrman, from the University of Pennsylvania Department of Psychiatry, for his gracious support during my dissertation.

To my dissertation committee, Drs. Holli Devon, Michael Calik, Eileen Collins and Mary Kapella, thank you for your patience and encouragement as I completed my dissertation at the NIH. I sincerely appreciate the time devoted to helping me through my project and the reinforcement all of you have provided over the years.

I would also like to thank other faculty members who I have been fortunate enough to have as mentors. To my constant cheerleader at UIC, Dr. Carrol Ferrans, your support has uplifted me when I

have needed it the most. I want to thank Drs. Collen Corte, Catherine Vincent and Laurretta Quinn for providing moral support and always listening and providing solutions to problems I faced along the way.

Additionally, I would like to thank my UIC colleagues, who have become some of my close friends. In particular, Susan Hovers, Katherine Breen, Katherine Erbe, Judie Hollman and Katherine Maki, my journey through this program would not be the same without all of you loving souls.

My dissertation would also not have been possible without the researchers, staff, and colleagues at NIH. Drs. Hyung-Suk Kim, Lai Chen and Ms. Chelsea Wagner, you make working in the lab easier and enjoyable. Thank you for always being a reliable resource and answering my questions about lab processing. Dr. SijungYun, thank you for being so patient and working with me on sequencing data. I appreciate the countless hours you have spent assisting me with analyzing data. Dr. Pamela Tamez, thank you for your support in all matters related to my training at the NIH. To my fellow officemate, Jackie Leete, thank you for all of your help with graphics and always being a breath of fresh air in times of stress. A special thank you to my dear friend, Dr. Meghan Murry, for supporting me through the ups and downs of life over the past year.

To my favorite Australian researcher and friend, Dr. Cassandra Pattinson, your work ethic and enthusiasm have always inspired me and I am grateful for our fun times together. Thank you for being my mentor and fellow sleep researcher and providing guidance during my dissertation. I am excited to see your career grow and I can't wait to see you again in the near future.

I would also like to thank my colleague, mentor and science enthusiast, Dr. Vivian Guedes. My experience at the NIH would not be the same without you. I am always grateful to brainstorm new research ideas with you, learn new techniques that are always way more involved than we think and grab a latte with you. You bring so much positive energy into my life and continuously motivate me to not shy away from things that may be difficult.

Lastly, and perhaps most importantly, I am wholeheartedly grateful for my family and friends who provided the much-needed emotional support that makes this process remotely possible. To my brother, Asif, you have been my rock since day one, support my every dream and make sure I am also enjoying life along the way. To my sister-in-law, Azmina, thank you for being a blessing in our house and supporting my needs during my education. To my childhood best friend and sister, Sarah Adtani, thank you for being a constant source of happiness over the many years. To my friends from Case Western Reserve University, Holly Johnson, Emily Kugel, Belle Perez, Shreya Sekaran, Liam McCormick, Zach March, Anthony Nguyen and Melissa Kelley, thank you for always encouraging me from day one and never letting distance affect our friendship.

To my fiancé and forever best friend, Fahad, I don't think I can ever convey how grateful I am to have your support through my education and training. Thank you for motivating me daily, encouraging me to pursue my dreams and being an anchor in my life.

Above all, my parents, Mansoorali and Rozina Mithani, there are no words to thank you for every sacrifice you have made to make sure I received the best education and opportunities possible. Thank you for always encouraging me to pursue my interests, wiping my tears at my lows and celebrating my success, no matter how big or small. Everything I am and have achieved is a direct reflection of you.

Thank you, God, for all your blessing to my family and me; for the strength you give me each day; for the opportunity to get an education and for all the people around me who make my life more meaningful.

SUMMARY

The purpose of this dissertation was to identify a transcriptomic profile of individuals with insomnia and explore the role of the glymphatic system and sleep disturbances in neurodegenerative disease and traumatic brain injury. The first paper reports whole blood transcriptomic analysis in individuals with insomnia using RNA sequencing technology. The study incorporated innovative high throughput sequencing platform with extended pathway analysis using QIAGEN's Ingenuity® Pathway Analysis software to identify differentially expressed genes and pathways in individuals with insomnia. The second paper provides a critical review of the sleep-wake process and the glymphatic system and how these processes contribute to neurodegenerative disorders and traumatic brain injury. The research addresses an important gap in knowledge about underlying mechanism of insomnia and how sleep disturbance, the glymphatic pathway and neurologic conditions may be interrelated.

1. Introduction

1.1 Background

In the United States, it is estimated that 50 to 70 million individuals of all ages and socioeconomic classes are affected by sleep-related problems. Insomnia occurs in approximately one-third of the population with 6-10% meeting the diagnosis for insomnia disorder.^{1,2} The Diagnostic and Statistical Manual of Mental Disorders, 5th Edition (DSM-5)³ defines insomnia as a predominant complaint of dissatisfaction with sleep quantity or quality associated with one of more of the following symptoms: 1) difficulty initiating sleep 2) difficulty maintaining sleep—characterized by frequent awakenings or problems returning to sleep after awakening and/or 3) early-morning awakening with the inability to return to sleep. The diagnosis is met if the sleep difficulty occurs at least 3 nights per week despite adequate opportunity to sleep and is not attributed to other physiological effects of substances such as drug abuse, alcohol or medications.⁴ The National Institutes of Health (NIH) has recognized that there is controversy around including nonrestorative sleep or sleep quality as part of the definition of insomnia as it is difficult to objectively characterize these terms.⁵ Although the definition of insomnia is still heavily debated, insomnia remains a highly prevalent disorder with substantial negative impacts on an individual's quality of life. In a study of 19,711 adults where health-related quality of life was measured with the short-form 8 (SF-8) questionnaire, individuals with insomnia had significantly lower physical and mental scores and a greater impairment score compared to individuals without insomnia.⁶ Moreover, the economic burden of insomnia is sizable, costing between 30 to 108 billion dollars per year with direct and indirect costs through prescription or over-the-counter medications,⁷ reduced work capacity and/or productivity,⁸⁻¹¹ low levels of work performance, increased absences from work, and injuries and illnesses.^{12,13} Although insomnia has debilitating consequences, little is known about the pathophysiological mechanisms of the disorder, under what conditions it progresses, or potential targets for prevention and treatment.

1.2 Pathophysiology of Sleep and Insomnia

A widely used operational definition of sleep is that it is a natural, reversible and self-regulated state characterized by a reduction in voluntary motor activity and decreased response to stimulation.¹⁴ The sleep-wake cycle is divided into three predominant states: wakefulness, non-rapid eye movement (NREM) sleep, and rapid eye movement (REM) sleep. NREM sleep is comprised of stages 1-3, with each stage involving unique characteristics. Following stage 3 NREM sleep, there is a transition to REM sleep. REM sleep includes rapid eye movements; increase variability in heart rate and blood pressure; and breathing is rapid, irregular, and shallow.¹⁵ The two-process model of sleep regulation proposes that homeostatic and circadian processes drive sleep.¹⁶ The homeostatic process (Process S), which builds during wakefulness and declines during sleep, interacts with a circadian process (Process C), which is independent of sleep and wake. During wakefulness, Process S increases exponentially, eventually reaching an upper threshold—the maximum propensity for sleep.¹⁷ Process S decreases during periods of sleep, reaching the lower threshold after approximately 8 hours of sleeping.¹⁸

The neural circuitry underlying the regulation of sleep and wakefulness is discrete but is uniquely interdependent. Wakefulness is maintained by an ascending reticular activating system which originates in the upper brainstem adjacent to the pons, midbrain and diencephalon where it then separates into two branches. The first branch innervates the thalamus and plays a gating role that can block the generation of thalamocortical rhythms and promote wakefulness.¹⁹ The second branch projects into the lateral hypothalamus, basal forebrain and cerebral cortex and plays a role in the discharging of neurons during wakefulness, NREM and REM sleep. Specifically, orexin/hypocretin neurons play a strong active role during REM sleep, and cholinergic neurons of the basal forebrain discharge at their maximal rates during REM sleep and active wake.¹⁹ Sleep-promoting neurons (e.g., histamine, dopamine, norepinephrine, serotonin, glutamate, orexin and acetylcholine) in the preoptic area, posterior lateral hypothalamus and in the lower brainstem inhibit the firing of neurons in the arousal area during sleep. Designed like a seesaw, the “flip flop” switch/circuit is created by mutual inhibition between the sleep promoting and the wake

promoting neurons, which allows for a rapid and complete transition between sleep and wakefulness.

Understanding the pathways of the sleep-wake cycle allows us to better understand how this cycle is altered in sleep disorders, chronic illnesses and drug interactions. Often considered to be a condition of hyperarousal, insomnia is associated with increased somatic, cognitive and cortical activation.²⁰

Physiological arousal may arise in both the central (cortical) and peripheral (autonomic) nervous system.

In addition, the neurobiological and physiological factors contributing to insomnia are likely multifaceted and may include additional factors such as environment, genetics, behavior, cognition and emotions.

Despite the high prevalence of insomnia, little is understood about the underlying mechanisms or how primary insomnia can be isolated compared to insomnia as a secondary symptom.

Recent studies show that sleep state is unique in the sense that it plays a key role in the clearance of metabolic waste in the brain that is collected during wakefulness.²¹ This system, known as the glymphatic system, utilizes a unique system of perivascular tunnels formed by astroglia cells to promote efficient elimination of aggregate proteins that can be toxic if accumulated in the brain. Xie et al. in 2013 demonstrated in both sleep and anesthetized mice that interstitial space volume was expanded to 22-24% compared to 13-15% during wakefulness.²² This observation indicates that the glymphatic function is particularly active during sleep and that the brain clears its waste products most effectively at this time. The developments of the glymphatic functions have been of particular importance to researchers as it may provide insight into how protein aggregation occurs in the brain thus leading to neurodegenerative conditions.

Additionally, the combination of monitoring sleep and glymphatic alterations can serve as a diagnostic marker for identifying individuals who may be at risk of developing further injury related complications.^{21,23} Further studies in human subjects need to focus on the neuroprotective properties of sleep as it relates to the glymphatic function in healthy controls and different disease processes.

1.3 Chronic Illnesses related to Insomnia

Numerous research studies have demonstrated increased prevalence of insomnia in individuals with somatic diseases^{12,21-23} and psychiatric disorders with anxiety and depression being the most common in individuals with insomnia²⁴⁻²⁷. For example, in an epidemiologic study with 7954 respondents, 40% of individuals with insomnia had a comorbid psychiatric disorder compared with 16.4% of those with no sleep complaints.²⁸ Additionally, complaints of insomnia are highly prevalent in individuals with cancer, chronic pain, and cardiovascular disease. A review article of 15 studies reported that 30% to 50% of individuals with cancer experience symptoms of insomnia.²⁹ A meta-analysis of 13 studies showed that individuals suffering from insomnia had a significantly increased risk (45%) of developing or dying from cardiovascular disease.³⁰ In recent years, sleep disturbances have been associated with neurological and neurodegenerative disorders, including Parkinson's disease and Alzheimer's disease. The cause of insomnia in neurodegenerative disease is multifactorial and includes the use of medications related sleep alterations (e.g., dopaminergic and anticholinergic treatment), the physiological effects from degenerative processes, and the natural aging process.³¹ Often, there is a bidirectional relationship between insomnia and these disorders, making it difficult to distinguish sleep disturbance as a primary disorder or secondary to another cause. Further research that explores these physiological alterations and mechanisms is needed to elucidate the role of sleep alterations in chronic illnesses.

1.4 Treatments of Insomnia

Treatment availability for insomnia include psychological, pharmacological, and alternative therapies. In 2005, a National Institutes of Health State-of-the-Science panel recognized cognitive-behavioral therapy (CBT) as a first-line treatment for insomnia. This therapy is aimed at modifying behavioral and thinking patterns that are presumed to prolong or exacerbate insomnia. Participants receive guidance to change sleep habits, sleep schedules and thinking pattern by trained mental-health clinicians.³² Although there is extensive data supporting the benefits of CBT-Insomnia (CBT-I) for sleep-onset and maintenance insomnia, contraindications of the therapy include daytime sleepiness, early

morning awakenings and adverse effects to sleep restriction such as manic phase or seizures. There are many different medications available to manage insomnia, but discovering the optimal pharmacological treatment that minimizes the treatment risk-benefit ratio varies for each patient based on the specific nature of their insomnia. Alternative therapies such as acupuncture are not generally recommended for the management of insomnia due to the lack of evidence about their potential benefits and risks.

Despite advances in pharmacological and behavioral treatments, many individuals with insomnia have recurrent symptoms, and some chronic and severe forms of insomnia are impervious to treatment. An increased understanding of the molecular mechanisms underlying insomnia is necessary to design novel and effective treatments for this disorder.

1.5 Transcriptome Profiling in Human Disease

The transcriptome contains the full information of all ribonucleic acid (RNA) transcribed in a specific tissue or cell type and their quantity for a specific developmental stage or physiological condition. The transcriptome allows for a comprehensive overview of gene structure, function, expression and plasticity.³³ Additionally, the transcriptome may reveal alterations in the biological processes triggering human disease thus offering insight into underlying mechanisms and also potential targets for diagnosis and clinical therapy. The recent development of high-throughput sequencing has provided new methods for mapping and quantifying the transcriptome. RNA-sequencing (RNA-seq) is the first sequencing method that allows for the entire transcriptome to be surveyed in a highly specific and quantitative manner. The complete RNA-seq procedure consists of three main components: experiment, bioinformatics, and additional analysis (Figure 1).³⁴ During the experiment preparation, RNA is isolated from tissue or blood samples and is converted to complementary deoxyribonucleic acid (cDNA) using reverse transcriptase. A library is constructed to identify and quantify all types of RNAs, and the cDNA is sequenced in a high-throughput manner to obtain short sequences at one end or both ends of the fragment. After the sequencing, the bioinformatics arm of the procedure is introduced. The sequence reads are put through a series of quality controls. The reads are then aligned to a genome based on the origin of the

sample with an RNA-seq aligner. During this process, the transcriptome is constructed. The constructed transcriptome is normalized and then statistical tests to identify differential genes are completed. Further analysis (e.g. cluster, visualization, pathway and network analysis and mathematical modeling) can be completed on the constructed transcriptome to gain further insight into the data.³⁴

1.6 Study Objectives and Hypothesis

The objective of this study was to identify differentially expressed genes and pathways associated with insomnia using RNA-seq technology. The high throughput sequencing method enables hundreds of millions of DNA molecules to be sequenced at one time. The advantage of this technology is that it can generate more comprehensive insight into the cellular genomic and transcriptomic signature of the disease and its developmental stages. Additionally, a nonsystematic review was conducted to review and synthesize new information of the glymphatic system and sleep. We also show how these mechanisms may be involved in two neurologic conditions, Alzheimer's disease and sleep, and its clinical relevance through discussing potential biomarkers for the conditions. The novelty of the review paper is that it is the first of its kind to tie together the overlap of sleep, glymphatic in respects to Alzheimer's disease and brain injury as it relates to clinically relevant biomarkers.

2.1 Introduction

Insomnia—difficulty falling and staying sleep—is a prevalent sleep disorder in the United States affecting between 10% and 20% of the population.^{1,2} The chronic sleep loss caused by insomnia can have many deleterious effects on health including effects on mood and anxiety disorders^{3,4}; respiratory⁵ and neurologic conditions^{6,7}; chronic pain^{1,8}; metabolic and cardiovascular disease^{9,10}; and diabetes.^{11,12} Insomnia has a significant economic burden, costing approximately \$30 to 108 billion dollars per year, a figure based on health consequences, work absences, and reduced productivity.¹³ Furthermore, it is well-documented that insomnia has a positive association with a broad range of negative health outcomes and decreased quality of life.¹⁴ Treatment options remains elusive, and the failure to treat insomnia is related to the lack of information about the biological mechanisms underlying this sleep disorder. An increased understanding of insomnia pathophysiology is needed before effective therapies can be developed.

Given the well-established associations of specific circadian (Clock, PER1, PER2, PER3, and Bmal1), inflammatory (cytokines/immune NF-kB, TNF, IL-1B, IL-6, IL10) and growth (growth hormone releasing hormone, Ghrelin Rho and Leptin epidermal growth factor) genes with sleep regulation identified in genome-wide association studies (GWAS), question arise of how changes in the expression of these genes may be associated with insomnia. GWAS identified five new genes (MEIS1, HHEX, RHCG, IPO7 and TSNARE1) and one locus (encompassing MEIS1) associated with insomnia.^{15,16} Specifically, the MEIS1 association signal identified was confirmed in all of UK Biobank samples (n=75,508 cases of frequent insomnia symptoms and 64,403 control).¹⁷ Saus et al., reported a common variant, rs76481776, located in the precursor form of miR-182 (found on CLOCK gene), was significantly associated with insomnia in patients with major depression.¹⁸ While these studies suggest a significant role for genes in insomnia, few studies have examined the expression of genes, specifically how gene-activity pathways relate to insomnia. Understanding patterns of gene expression, through transcriptomics, may provide insight into the multifaceted variations in traits that relate to insomnia, yet

these possible links remain largely underdetermined. The transcriptome offers important information about gene structure, expression and regulation. Understanding these processes may be essential for interpreting the elements of the genome and the role these elements may play in disease processes such as insomnia.

Multiple approaches were developed for measuring the transcriptome; in recent years, however, RNA sequencing was recognized as an optimal method for capturing the transcriptome dynamics across different tissue types.¹⁹ More specifically, RNA-seq supports both the discovery and quantification of transcripts using a single high-throughput sequencing assay with high specificity and sensitivity,²⁰ yet few studies have used this method to determine gene-activity pathways that relate to sleep disturbance in clinical samples.

The aim of this study was to identify transcriptomic profiles by comparing RNA sequencing in the whole blood of individuals with and without insomnia. We hypothesized that there would be distinct, measurable differences in gene expression levels between individuals with and without insomnia.

2.2 Methods

To conduct this study, samples were acquired from a completed case-control study comparing 15 subjects with primary insomnia and 15- age and gender- matched “good sleeper” controls.²¹ Participants between the ages of 25 and 50 and free of significant medical or psychiatric comorbidity were recruited from the community. Witnessed written informed consent was obtained from each participant at the University of Pennsylvania Clinical and Translational Research Center. Research diagnostic criteria for primary insomnia were as follows: self-reported complaint of difficulty initiating or maintaining sleep, waking up too early or nonrestorative sleep; daytime consequences as a result of the poor sleep; duration of at least 1 month; sleep disturbance is not secondary to a medical or psychiatric condition. Exclusion criteria included: significant medical or psychiatric illness (e.g. major depression or chronic pain) based on clinical history of psychiatric interview, evidence or diagnosis of sleep disorder other than insomnia as determined by clinical history or polysomnography screening, current shiftwork (working during the

evening or night shift), current use medications or over the counter products, or body mass index (BMI) >27. Questionnaires were collected at the first visit for information on demographics, sleep quality, and psychological functioning including the Insomnia Severity Index (self-report estimate of sleep disturbance)²², the Trait portion of the State-Trait Anxiety Inventory²³, and the Quick Inventory of Depressive Symptomatology – self-report version.²⁴ A detailed description of the parent case control study has been previously published.²⁵

2.2.1 Sample Processing

Blood samples from study participants were collected in PAX gene blood RNA tubes at 0900 via an indwelling intravenous catheter. Blood tubes were stored at -80°C until all samples had been collected and then were processed as a batch. RNA was extracted from blood samples using the PAXgene Blood miRNA kit (PreAnalytiX). Purified RNA samples were prepared with TruSeq Stranded Total RNA with Ribo-Zero Globin Kit (Qiagen). The library was sequenced with the 150 bp paired-ends on the Illumina NovaSeq-6000 platform.

2.2.2 Statistical Analysis

Quality control for the raw reads were performed with FASTQC version 0.11.8, and adapter trimming was done with BBDOUK in BBTOOLS version 38.42. Spliced alignment for the reads to the human reference genome hg38 using STAR version 2.7.2a with default parameters. The percentage of mapped reads ranged from 86.2% to 93.1%. Differential gene expression analysis was performed using DESeq2 version 1.24.0. DESeq2 provides methods to test for differential expression by use of the negative binomial distribution and a shrinkage estimator for the distribution's variance. P-values are generated using a modified Fisher's exact test provided within DESeq2 and further corrected for multiple hypothesis testing using the Benjamini-Hochberg correction method to decrease the false discovery rate (FDR). Significant differential expressed genes were yielded at a FDR of 5% and a minimum fold-change of 1.3x. Pathway analysis was performed using QIAGEN's Ingenuity® Pathway Analysis (IPA) software (build version 389077M, released 2019-08-30, content version 27821452, Qiagen, Redwood City, CA).

2.3 Results

2.3.1 Demographic and Clinical Characteristics

Table I provides a summary of the demographic and clinical characteristics of the sample. Participants with insomnia (n=15) and good sleepers (n=15) were between the ages of 25-50 years (insomnia group Mean = 39.20, SD = 9.59 years; control group Mean = 36.07, SD = 7.96 years). Each group had 5 males and 10 females with participants identifying as white (66.67%), African American (26.67%), or Asian (6.67%). The insomnia group's mean (SD) Insomnia Severity Index (ISI) was 15.14 (2.37) and the good sleeper group's mean (SD) ISI was 1.73 (4.72). The Quick Inventory of Depressive Symptomatology mean (SD) was 5.67 (2.95) for individuals with insomnia and 1.27 (1.34) for good sleepers, and the State-Trait Anxiety Inventory (trait portion) was 30.6 (8.47) and 26.2 (4.84) for insomnia and good sleepers respectively. Both the ISI and the Quick Inventory of Depressive Symptomatology mean scores significantly differed between the insomnia group ($p < .001$, $r = .815$) and control group ($p < .001$, $r = .699$).

2.3.2 RNA-Seq and Network Analysis

We obtained an average of 31.2 million 150 base pair (bp) paired end reads per sample. Of those, an average of 89.7% of the read pairs mapped to the reference genome (hg38). We examined differential expression of aligned reads using DESeq2, and a gene was identified as differentially expressed if it showed a log fold change (LFC) ± 0.50 and had a FDR p-adjusted < 0.05 . The majority of the differentially expressed genes were identified as protein coding genes (Figure 2). Out of the 45,233 genes with nonzero total read count, there were 288 significantly differentially expressed genes between individuals with insomnia and normal controls (Figure 3). Top 3 significantly upregulated genes included LINC02224 ($FC_{lg2}=5.289$, $P_{adj}= 0.012$), DUX4L9 ($FC_{lg2}=3.404$, $P_{adj}= 0.005$) and TUSC3 ($FC_{lg2}=3.352$, $P_{adj}= 0.033$). Highest significantly down regulated genes were CTXN2 ($FC_{lg2}=-2.861$, $P_{adj}= 0.031$), CSMD1 ($FC_{lg2}=-2.377$, $P_{adj}= 0.001$) and SLC12A1 ($FC_{lg2}=-2.140$, $P_{adj}= 0.009$).

To examine interactions of the differentially regulated genes with other gene products, we formed molecular networks in IPA using functional relationships. IPA illustrates non-deregulated genes with no color, up-regulated genes in red and down-regulated genes in green. 143 up regulated and 145 down regulated genes were used to generate IPA networks. Five significant networks were identified between participants with insomnia versus controls; however only we chose to focus only on the top 3 networks, which had IPA network scores above 40 (Table II). In this study, score of >40 was deemed as significant, which is equivalent to the p-value of 10^{-40} . Genes reported in the network are reported in Table III (upregulated) and Table IV (downregulated).

1 Network 1: The highest scoring candidate network centered on hematological diseases, hereditary disorders, organismal injuries and abnormalities (Figure 4). The top three up regulated genes were HBD (Log 2 Fold Change [FC_{lg2}] = 2.207, p_{adj} = 0.001), HBG1 (FC_{lg2} = 2.015, p_{adj} = 0.001) and HBB (FC_{lg2} = 1.838, p_{adj} = 0.004). The top downregulated gene was LY96 (FC_{lg2} = -0.731, p_{adj} = 0.017). This network consisted of multiple upregulated hub genes (IgG, HBA1/HBA2, IGHG2 and hemoglobin) and non-deregulated hubs (Immunoglobulin, Ige, Fc gamma receptor, BCR complex and NFkB complex).

2 Network 2: Network 2 genes were related to developmental disorder, metabolic disease and hereditary disorders (Figure 5). Of the 22 genes identified in the network, there were 8 mitochondrial genes identified. The highest fold changes were observed in MUC5AC (FC_{lg2} = -1.550, p_{adj} = 0.024) and MUC2 (FC_{lg2} = 2.021, p_{adj} = 0.024). UTS2 (FC_{lg2} = -0.655, p_{adj} = 0.014) was identified in this network and has been previously associated with insomnia in military populations²⁶. Key hub genes in this network include: growth hormone, cytokine, TACR1, STAT5a/b, ERK1/2 and Rock.

3 Network 3: This network encompassed genes related to cell cycle, cell mediated immune response and cellular development (Figure 6). Three genes had a fold change > 2.0: SIAH2 (FC_{lg2} = -2.140, p_{adj} = 0.009), PTPRU (FC_{lg2} = -2.138, p_{adj} = 0.002) and NCAPG (FC_{lg2} = 2.178, p_{adj} = 0.013). Eleven nonregulating complexes were identified including two histone complexes (Histone h3 and h4), TCR,

ERK, CD3, caspase, 26s Proteasome, Ubiquitin, Hdac, Rb, and E2f. SQSTM1, PRKDC and TCF3 were downregulated hub genes; CDC6 and CCNA2 were upregulated hubs.

2.4 Discussion

We determined that insomnia was associated with differential gene expression by comparing insomnia patients to matched controls who were good sleepers. Our study identified unique gene-pathways, such as inflammatory, ubiquitin and oxidative stress pathways, that relate to insomnia. These novel findings provide insight into the transcriptomic changes associated with insomnia and may shed light alterations of biological process in insomnia and mechanisms underlying the disorder. Network analysis identified 5 candidate networks with the top 3 networks further examined. The differentially expressed genes identified within the IPA networks are also known to be related to inflammatory, metabolic disease, immune function and mitochondrial dysfunction.

In network 1, nuclear factor- κ B (NF- κ B) complex was a hub gene with indirect associations to multiple dysregulated genes (e.g. TNFSF13B and LY96) and complexes (e.g., IgG and Ige), all of which play a role in inflammatory response (Figure 3). Representing a family of inducible transcription factors, NF- κ B regulates a large array of genes involved in immune and inflammatory responses.²⁷ Sleep loss has been shown to enhance cortical NF- κ B activation in mouse brains.²⁸ Additionally, NF- κ B has been observed to be greater in the morning after sleep loss.²⁹ Indirectly associated with NF- κ B complex in Network 1, upregulated gene LY96 encodes a protein that is associated with toll-like receptor 4 and confers interaction with lipopolysaccharides (LPS) on the surface of immune cells, causing the secretion of pro-inflammatory cytokines.³⁰ Reduced sleep time and fragmentation has been linked to increases in LPS signaling, increases in permeability of the epithelial barriers and can also cause alterations in gut microorganisms.³¹ Research indicates that the immune and inflammatory pathways are implicated in the regulation of homeostatic functions, including sleep.³² Additionally, sleep loss has been associated with the activation NF- κ B molecular pathway resulting in inflammatory gene expression and the increased risk of inflammation-related diseases.²⁹ Thus, these outcomes support the finding of an association between

insomnia and inflammation. Longitudinal tracking of people at risk for insomnia is needed to determine the direction of this effect.

Previous research has associated mitochondrial dysfunction and oxidative stress to insomnia, an association that was further supported by Network 2. In this analysis, a smaller up-regulated network of mitochondrial genes (MT-ND1,2,4,5,6, MT-RNR1, MT-CYB) were associated with insomnia. Specifically, in this network, there was an upregulated Mitochondrial complex 1 and nicotinamide adenine dinucleotide (NADH) hydrogenase (Figure 4). Mitochondrial complex 1 is responsible for the first step in the electron transport process, the electron transfer from NADH to ubiquinone and then through several other complexes to provide energy for ATP synthesis.³³ The genes identified in this network are implicated in oxidative stress. Oxidative stress occurs when there is an imbalance in the oxidative-redox system, either because the production has increased or decreased, and this process plays an important role in the development of diseases such as autoimmune disorders, cancer, aging, cardiovascular, neurodegenerative diseases and psychiatric disorders.³⁴⁻³⁷ Gulec et al., found that poor sleep quality led to higher levels of oxidative stress factors in individuals with primary insomnia.³⁸ Additionally, previous research has consistently concluded both that sleep may have a protective role against oxidative damage and that sleep loss is an oxidative challenge.^{38,39} The STAT (signal transducer and activator of transcription) protein family cross talks with major cytokine signaling pathways like NF- κ B. STAT 5a/b (nonregulatory, Network 2) is associated with growth hormone, cytokines and mitochondrial complex. In 24 healthy participants who underwent partial sleep loss (0300-0700 hours) there was an activation of STAT family proteins after sleep recovery.⁴⁰ Moreover, previous research has shown that STAT proteins act as a key signaling cascade mediating cytokine receptor derived signals and growth factors.⁴¹

UTS2 (upregulated, Network 2) encodes for the neuropeptides orexin A and B, which are involved in the regulation of sleep. Gill et al. (2017) identified 44 transcripts and 43 genes comparing military personnel with and without insomnia using microarray technology. Among the identified genes,

urotensin 2, which is involved in the regulation of rapid eye movement sleep, was downregulated 6-fold in individuals in insomnia.²⁶ Taken together, our findings in Network 2 support previous studies linking insomnia to mitochondrial dysfunction and suggests that interventions to address these biological markers may provide new avenues to treat insomnia. Protein ubiquitination regulates various biological processes protein, such as kinase activation and DNA repair, not only through targeting degradation of proteins by proteasome but also by regulation of protein function.⁴² For example, protein ubiquitination is required for the removal of oxidized or misfolded proteins that accumulate as a result of neuronal function during wakefulness. Lack of clearance and removal of these oxidized or misfolded proteins has been linked to cognitive impairment in individuals with insomnia²⁶ and Alzheimer's disease.⁴³ Additionally, ubiquitination has been shown to play a role in insomnia phenotype through the activity of E3 ubiquitin ligase Cul3⁴⁴ and may disrupt circadian rhythm via Ubiquitin C-terminal hydrolase L1.⁴⁵ In Network 3, the ubiquitin complex has a direct association with SQSTM1 (also known as Ubiquitin-Binding Protein P62) which has been shown to play a regulatory function in ubiquitin-mediated proteolysis (Figure 7). SQSTM1 has also been associated with protein aggregation in neurodegenerative disorders of aging including Alzheimer disease (AD), Parkinson disease (PD), Huntington disease (HD), amyotrophic lateral sclerosis (ALS), frontotemporal dementia (FTD) and related tauopathies.^{46,47} Comorbid insomnia and sleep disturbances are common in individuals with neurodegenerative conditions.^{6,48} Although insomnia may be a secondary factor associated with the condition such as pain, depression or side effects of medication, insomnia may also be a direct consequence of the disease. FANCL (upregulated, Network 3) is a ubiquitin ligase that is a member of the Fanconi anemia complementation group. Fanconi anemia is a genetic disorder that is characterized by hypersensitivity to DNA crosslinking agents, increased chromosomal breakage and defective DNA repair⁴⁹. The current findings in Network 3 extend previous research in the role of ubiquitination as a mediator of sleep-related gene activity in insomnia.

This study's limitations, including a relatively small samples size and a lack of diversity found in the general population of people with insomnia, may limit generalizability of the findings. However,

given the case control study design, we were able to examine age- and sex- matched group of individuals with and without insomnia, who did not use medications nor have any additional comorbidities. This enabled us to investigate the potential role of multiple genes in insomnia while limiting potential confounding factors. An important strength of the present study was the use of a novel and high throughput RNA-seq technology for the analysis of gene expression at the level of the whole transcriptome. Additionally, whole blood samples have been recognized to be a useful surrogate of gene expression in the peripheral and central nervous system and can be collected in a minimally invasive manner that is amenable for potential future diagnostic test development.⁵⁰ Therefore, while the present study provides important initial findings of differentially expressed genes for insomnia, subsequent investigations should aim to recruit larger groups of subjects representing the diverse demographic characteristics of the U.S. population. Our novel methodological approach can be used to understand the genetic mechanisms and dysregulation underlying insomnia.

2.5 Conclusion

To our knowledge, this was the first study to analyze transcriptomic gene expression variation using peripheral blood in individuals with insomnia. Our study identified potential differences in gene expression that distinguished subjects with insomnia from controls indicating differences in inflammation/immune, mitochondrial, metabolic, and inflammatory signaling pathways. Identification of dysregulated pathways in insomnia may provide novel insight to the pathophysiology of the disorder and the mechanisms through which insomnia negatively affects an individual's physical and mental health. Further research into the transcriptomics of insomnia is warranted to further understand the different pathways associated with insomnia and so that new avenues of treatment can be explored.

* Denotes non-protein coding gene

Figure 2. Pie chart of protein coding and non-protein coding gene.

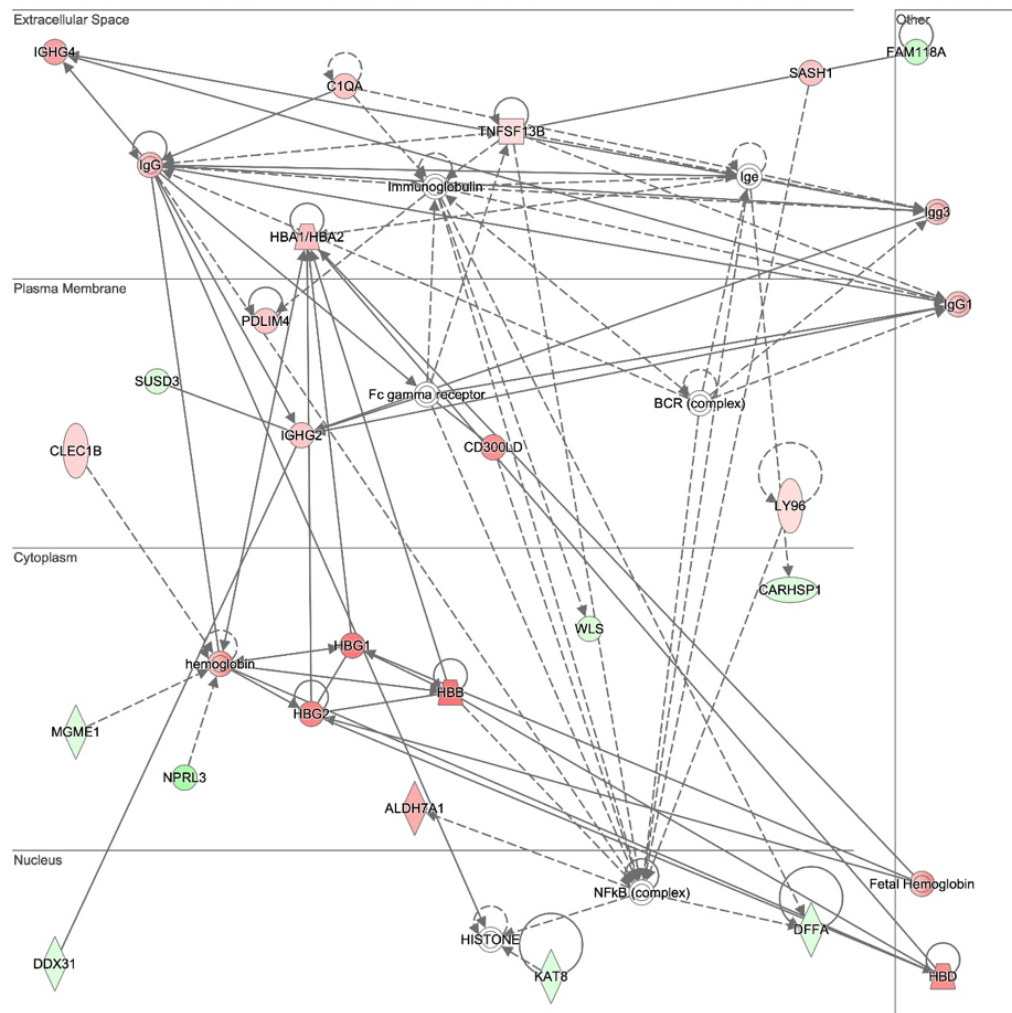

Pie chart depicting protein coding and non-protein coding gene types for individuals with insomnia and controls.

Figure 3. Volcano plot of dysregulated genes identified by RNA-sequencing.

Black dot indicates non-significant gene and red indicates significant gene yielded at a false discovery rate of 5% and a minimum fold-change of 1.3x.

Figure 4. IPA Network 1

Green indicates that the gene is downregulated. Red indicates that the gene is upregulated, with increased color saturation representing more extreme measurement in the dataset. Solid lines represent interactions, non-targeting interactions, or correlations between chemicals, proteins, or RNA. Arrowed lines represent activation, causation, expression, localization, membership, modification, molecular cleavage, phosphorylation, protein-DNA interactions, protein-TNA interaction, regulation of binding, transcription. Shapes represent molecule type (double circle=complex/group; square=cytokine; diamond=enzyme; inverted triangle=kinase; triangle=phosphatase; oval=transcription regulator; trapezoid=transporter; circle=other).

Figure 5. IPA Network 2.

Green indicates that the gene is downregulated. Red indicates that the gene is upregulated, with increased color saturation representing more extreme measurement in the dataset. Solid lines represent interactions, non-targeting interactions, or correlations between chemicals, proteins, or RNA. Arrowed lines represent activation, causation, expression, localization, membership, modification, molecular cleavage, phosphorylation, protein-DNA interactions, protein-TNA interaction, regulation of binding, transcription. Shapes represent molecule type (double circle=complex/group; square=cytokine; diamond=enzyme; inverted triangle=kinase; triangle=phosphatase; oval=transcription regulator; trapezoid=transporter; circle=other).

Figure 6. IPA Network 3.

Green indicates that the gene is downregulated. Red indicates that the gene is upregulated, with increased color saturation representing more extreme measurement in the dataset. Solid lines represent interactions, non-targeting interactions, or correlations between chemicals, proteins, or RNA. Arrowed lines represent activation, causation, expression, localization, membership, modification, molecular cleavage, phosphorylation, protein-DNA interactions, protein-TNA interaction, regulation of binding, transcription. Shapes represent molecule type (double circle=complex/group; square=cytokine; diamond=enzyme; inverted triangle=kinase; triangle=phosphatase; oval=transcription regulator; trapezoid=transporter; circle=other).

3. A Review of the Glymphatic System and its Implications for Alzheimer's Disease and Brain Injury Research

3.1 Introduction

Sleep is a vital function, necessary for immunity, tissue growth and repair, and memory.¹ During sleep, the brain remains metabolically active. The brain lacks lymphatic vessels, and therefore metabolites and proteins, that are the waste products of brain metabolism, are transported into the interstitial fluid (ISF) and cerebrospinal fluid (CSF). A clearance pathway unique to the central nervous system—the glymphatic system—was first defined by Iliff et al. in 2012.² The glymphatic pathway is more active during slow wave sleep periods compared with wakefulness. This observation suggests that conditions that disrupt sleep (e.g., insomnia, brain injuries, neurodegeneration) could adversely affect glymphatic processes and impair brain function. Dysfunction of the glymphatic system may play a role in pathophysiology of neurodegenerative diseases, such as Alzheimer's disease (AD), in which the accumulation of amyloid beta (A β) contributes to progressive deficits.^{3,4} Traumatic brain injury (TBI) pathophysiology may also impair glymphatic mechanisms, and it remains unknown whether impaired clearance of metabolites via the glymphatic pathway contributes to the deficits affecting patients with TBI.

A understanding of the glymphatic clearance of metabolic waste products is critical for achieving an improved understanding of conditions, such as AD and TBI, and for identifying novel biomarkers that measure disease development and progression. The purpose of this review was to examine knowledge about the functions of the glymphatic system during sleep versus wakefulness and define the implications for AD and TBI research.

3.2 What is the glymphatic system?

The glymphatic system, is a highly polarized and organized system of continuous cerebrospinal fluid (CSF) and interstitial fluid (ISF) interchange. Blood is separated from the CSF and ISF by the blood-brain-barrier (BBB) and the blood-CSF barrier. The BBB is comprised of blood vessel endothelial cells coupled by tight junctions, restricting macromolecules to move freely between the blood into the

brain parenchyma. The blood-CSF barrier is formed by tight junctions between the choroid plexus epithelial cells.^{5,6} This continuous interchange of fluids is facilitated by CSF moving from the subarachnoid space to the perivascular space, also known as the Virchow-Robin space.^{3,7} The influx of CSF is facilitated by a combination of arterial pulsatility, slow vasomotion, and the CSF pressure gradient. The CSF from the Virchow-Robin space continues to flow into the perivascular space around the arterioles, capillaries and venules. Astrocytic vascular endfeet expressing aquaporin-4 (AQP4), expressed highly in the brain vasculature and form the boundary of the perivascular space, transport the CSF from the perivascular space into the brain parenchyma. Glial AQP4 channels play an important role in the macroscopic waste clearance by enabling fluid exchanges between the CSF and the brain parenchyma interstitial fluid (Figure 7).^{2,3,5,6} Each of these components make up the glymphatic system and enable the clearance of waste products from the CNS.

One of the first hallmark studies of the glymphatic system completed by Iliff and colleagues in 2012² demonstrated that a substantial amount of subarachnoid CSF cycles through the interstitial space in the brain using in-vivo two photon imaging of small florescent tracers. They further demonstrated in transgenic mouse models that when AQP4 channels in astrocytes are removed from the brain, there is an approximate 70% reduction in interstitial solute clearance, suggesting that AQP4 channels play a key role in the fluid flow of CSF and ISF in the brain. Moreover, fluorescently tagged amyloid beta protein, a metabolic waste product, was shown to be transported from the ISF and then out of the brain, suggesting that the glymphatic flow plays a role in the clearance of metabolic products whose buildup is associated with neurodegenerative conditions. This then led to studies that showed brain glymphatic functions increase as much as two-fold times after sleep than during wakefulness. Xie et al., conducted in-vivo 2 photon imaging of glymphatic influx in the mouse cortex.⁸ CSF influx in the wake state was reduced by 90% compared to a natural sleep and anesthetized state.⁸ Additionally, sleep had a greater difference in glymphatic influx correlated with the volume fraction of interstitial space compared to wakefulness, from 22-24% to 13-15% respectively.⁸ This observation indicates that the interstitial space volume increases in sleep, allowing for CSF-ICF exchange to clear metabolites and neurotoxic waste

products produced during wakefulness (Figure 8). When looking at these findings together, this information suggest that sleep enhances the metabolic waste clearance in the brain and that dysregulation of the glymphatic flow can lead to aggregation of waste products in the brain thus increasing risk of neurodegenerative conditions.

3.3 Neurodegeneration: Alzheimer's Disease

One disease that has shown an association with glymphatic is Alzheimer's disease, which is a neurodegenerative disorder characterized by loss of memory, difficulty completing familiar tasks, mood and behavioral changes.⁹ Although progressive memory loss is a hallmark clinical symptom of AD, physiological alterations in the brain can be found as part of the normal aging process. Approximately 25 million individuals suffer from dementia,¹⁰ of whom most suffer from Alzheimer's disease, with physiological alterations attributed to age-related accumulation of fibrillary protein aggregates such as extracellular senile plaques (amyloid B-A β) and intracellular neurofibrillary tangles (hyper-phosphorylated tau).⁴ A β , which plays a physiologic role in synaptic regulation, neuronal growth and repair, is degraded and removed through multiple pathways.^{11,12}

3.3.1 Sleep/wake disruption in AD

There is growing evidence that sleep disturbances may contribute to AD by facilitating accumulation of A β in the brain. Complaints of sleep changes and circadian disruption are common in AD and severity of disruption is parallel to the severity and progression of the disease.¹³ Individuals experience difficulties falling asleep, maintaining sleep, fragmentation of sleep and endure excessive sleepiness during the day.¹⁴ Sundowning syndrome, a sleep-wake cycle alteration, is a symptom in AD that manifests with increments of neuropsychiatric conditions in the late afternoon, evening or at night. The disruption in the circadian process alters sleep patterns, core body temperature¹⁵ and imbalance in hormone secretion. In addition to physiologic alterations, exogenous factors, such as pain, pharmacologic drugs, cardiac, respiratory and gastrointestinal distress, may be responsible for sleep disturbances in patient with AD, especially when looking at long-term care.¹⁶ In a study with 20 healthy individuals who

underwent one night of sleep deprivation, PET scans revealed significant A β after one night of sleep deprivation compared to rested sleep.¹⁷

3.3.2 Role of glymphatic system in AD

Prior research has proposed that the glymphatic pathway could play a substantial role in the net clearance of A β .² Transgenic mouse models exist that mimic a range of AD-related pathologies allowing researchers to investigate pathophysiology of the disease process. In a AQP4 knockout mouse model, impaired glymphatic function resulted in a 55% reduction in the clearance of radiolabeled ¹²⁵I A β ₁₋₄₀ compared with clearance in wildtype mice.² However, in 12-month old AQP4 gene knockout (AQP4^{-/-}) A β precursor protein/presenilin 1 (APP/PS1) transgenic mice, the deletion of AQP4 had a tendency to reduce neuroinflammation but exacerbate brain A β accumulation and cognitive dysfunction.¹⁸ Moreover, paravascular A β clearance is regulated by sleep-wake cycle, which is often disrupted in patients with AD. Burfiend et al. conducted a human genetics study with 634 individuals with and without AD, five AQP4 single-nucleotide polymorphisms (SNPs) were associated with cognition and functional decline in AD.¹⁹ Four of the five SNPs identified, rs3763043, rs3763040, rs9951307, and rs3875089, were associated with slow to rapid decline in cognitive function and functioning. Conversely, Rs335929 was associated in slower cognitive decline but faster functional decline.

Rainey-Smith and colleagues conducted a cross-sectional observational study in older adults with normal cognitive functioning where genetic variation of AQP4 (measured by SNP data from the AQP4 genomic region), was compared to overall sleep quality (measured by the Pittsburgh Sleep Quality Index), sleep latency (time it takes to fall asleep), sleep duration and brain A β burden (measured via positron emission tomography (PET) using one of the following radiolabeled A β tracers).²⁰ The study revealed that several AQP4 SNPs moderated the effect of sleep latency (rs491148, rs9951307, rs7135406, rs3875089, rs151246) and duration(rs72878776, rs491148 and rs2339214) on A β burden. Findings suggest that variation in AQP4 moderates the association between sleep and A β burden. Although further mechanistic studies are needed to understand the role of AQP4 and the glymphatic pathway in AD, these findings suggest that variations in the AQP4 gene can alter the clinical presentation and course of AD.

3.3.3 Biomarkers in AD

In AD, CSF biomarkers of A β plaque pathology and as well as neuronal phosphorylated-tau (p-tau) are associated with neurodegeneration and tau pathology. Biomarkers of A β plaque are measured with reduced concentration of CSF A β 42 or A β 42/40 ratio due to the selective retention of A β in brain tissue.²¹ Moreover, total tau (T-tau) and p-tau can be measured in CSF. Although CSF based biomarkers for AD have been part of clinical practice, CSF collection (through lumbar puncture) is an invasive process, undoubtably making blood based testing the preferred method of biomarker measurement.

Several independent studies suggest that blood plasma A β 42/40 ratio reflects A β pathology in the brain. Immunoassays for measurement of A β 42 in plasma are based on the ultrasensitive digital enzyme-linked sandwich immunoassay (ELISA)^{22,23} or the Luminex²⁴ techniques. Single-cell molecular (Simoa) A β 42 assay breakthrough provides highly sensitive, precise and reproducible A β 42 measurement in blood plasma and serum.²⁵ Simoa technology has also identified ultrasensitive measures for T-tau in plasma.²⁶ In addition, neurofilament light chain (NfL) is a biomarker that can be measured with immunoassays with CSF, plasma and serum. NfL reflect axonal damage in a variety of neurodegenerative diseases including AD, Huntington's disease and frontotemporal dementia.²⁷ Ashton et al., (2019) conducted a longitudinal study where blood plasma NfL (collected at two time points) was compared to participants post-mortem brain tissue neurofibrillary tangles.²⁸ 12 cognitively health individuals and 57 individuals with AD who participated in the study. Plasma NfL levels were significantly higher in AD compared to cognitively healthy subjects at both time points ($p < 0.01$). Additionally, plasma NfL was elevated with increasing severity of AD, which was classified by post-mortem pathology and plasma NfL increased over time independent of post-mortem tangle pathology. Overall, these studies provide evidence that blood plasma measurement of A β and NfL may be an accessible clinical biomarker for neurodegeneration.

3.4 Neurovascular: Traumatic Brain Injury

Approximately 1.7 million individuals suffer a traumatic brain injury (TBI) each year.²⁹ Military personnel have seen an increase in TBI and it has been classified as the signature injury of troops serving in Iraq and Afghanistan.³⁰ TBI may be caused by a bump, blow or jolt to the head or a penetrating head

injury that disrupts normal brain function.³¹ Clinical presentation and symptoms vary by severity of injury, ranging from loss of consciousness, headache, dizziness, nausea and even death. Furthermore, many initial features of the injury do not transfer into long-term consequences making biomarkers beneficial for diagnosis and treatment of the injury.³²

3.4.1 Sleep/wake disruption in TBI

TBI is strongly associated with several sleep–wake disturbances with the most common being insomnia and hypersomnia.³³ Characterized by difficulty maintaining or initiating sleep, insomnia is reported in 30-60% of individuals following TBI of all severity.³⁴ In a study with 452 participants who suffered from mild to severe TBI, 50.2% of participants reported insomnia symptoms and 29.4% of individuals met the criteria for a insomnia diagnosis.³⁵ In deployed military personnel who completed self-reported measures of insomnia and clinical interviews, compared to controls who reported insomnia, individuals with single TBI were four times more likely and individuals with multiple TBI were 10 times more likely to exceed the threshold for clinical insomnia compared to military personnel with no history of TBI.³⁶ Hypersomnia, which refers to either excessive daytime sleepiness or excessive time spent sleeping, has been significantly prevalent in the acute period following TBI.^{37,38} Individuals with more severe TBI injuries have a greater association with sleepiness. Although, sleepiness may improve in many patients overtime, it may persist in up to a quarter of patients 1 year after injury.³⁹ There is a large body of literature now that describes sleep-wake disturbances and disorders associated with TBI however there is limited research that provides clues to the underlying pathophysiology of changes.

3.4.2 Role of glymphatic system in TBI

Previous research has given insight that TBI disrupts the BBB resulting in diffusion of biomarkers into blood circulation.^{40,41} Brain injury causes disruption of the tight junction complexes and the integrity of membranes resulting in increased paracellular permeability.⁴² This causes oxidative stress and increases the production of proinflammatory mediators and there is an increase inflammatory cells to the injured brain parenchyma.⁴³ In a closed-skull moderate TBI model in adult male mice, glymphatic pathway function was reduced by 60% after TBI, with impairments persisting for at least 1 month after

injury.⁴⁴ Additionally, there was a loss of perivascular AQP4 polarization resulting in impairment of glymphatic pathway which is a key feature of astrocytes reacting to the injury.⁴⁴

3.4.3 Biomarkers in TBI

Potential biomarkers for TBI have been well researched in hopes that the cellular factors identified in the blood may be used to measure the severity of brain injury although limited biomarkers have advanced to the clinical setting. Some of the most widely studied blood biomarkers for TBI include protein biomarkers for neuronal cell body injury (Ubiquitin C-terminal hydrolase-L1 (UCH-L1), Neuron specific enolase (NSE)),⁴⁵⁻⁴⁷ astroglial injury (glial fibrillary acidic protein (GFAP), S100B),⁴⁸⁻⁵⁰ neuronal cell death (α II-spectrin breakdown products), axonal injury (Neurofilament (NF) proteins), white matter injury (Myelin basic protein (MBP)), post-injury neurodegeneration (total Tau and phospho-Tau) and post-injury autoimmune response (brain antigen-targeting autoantibodies).⁵¹

A new 4 marker panel, including copeptin, galectin-3, matrix metalloproteinases-9 (MMP-9), and occluding, was recently developed to aid in the diagnosis of mTBI and concussion. Copeptin, a glycopeptide, is a part of a precursor peptide of arginine vasopressin and neurophysin II produced by hypothalamic neurons and can be used as a marker for individual hemodynamic stress response.⁵² The measurement of copeptin has been useful in diagnosis of diabetes insipidus⁵³ and monitoring of cardiovascular disease⁵⁴ and sepsis.⁵⁵ Galectin-3, a pro-inflammatory lectin family member, plays an important role in numerous biological activities including cell growth, apoptosis, pre-mRNA splicing, transformation, angiogenesis, inflammation, fibrosis and host defense. Previous studies have found galectin-3 as a potential diagnostic and prognostic biomarkers for certain types of heart disease (heart failure,⁵⁶ coronary artery disease, atrial fibrillation and hypertension),^{57,58} renal disease⁵⁹ and cancer.⁶⁰ MMP-9, a collagenase enzyme, directly degrades extracellular matrix and activates cytokines and chemokines to regulate tissue remodeling.⁶¹ Recent advances in research has highlighted MMP-9 as a potential biomarker for certain cancers⁶² and cardiac remodeling.⁶³ Occludin, an integral tight junction protein, is a key structural component of the blood-brain-barrier.⁶⁴ Rapid loss of occluding contributes to BBB disruption and is frequently seen with ischemic stroke.^{65,66} The 4 candidate plasma biomarker was

tested in adults who sustained a concussion within 24 hours of enrollment and controls, which comprised of uninjured patients and patients with orthopedic injury. All 4 markers had a significant increase when comparing injured individuals to healthy controls. Galectin-3 and occluding levels correlated positively in patients with mTBI but not in patients with orthopedic injury or uninjured controls, which may aid in the diagnosis of suspected mTBI.⁶⁷

In addition to protein biomarkers, miRNA profiling may provide valuable information into the mechanisms of normal cellular function and disease process. miRNA, found in extracellular vesicles, are small non-coding RNAs that regulate gene expression at the post-transcriptional level.⁶⁸ They are highly expressed in the brain, are stable in peripheral biofluids such as blood, saliva, urine and can cross the BBB. miRNA profiling and detection provide valuable information on their essential roles in normal cellular function and disease, projecting their use in the clinical practice for the diagnosis and prognosis of several pathologies. Recent reports indicate a host of miRNA candidates that may be representative of CNS injury across a spectrum of severity and time. For example, in a cohort of male athletes who suffered a sports-related mTBI, five salivary miRNA based biomarkers (miR-27b-3p, let-7i-5p, miR-142-3p, miR-107, miR-135b-5p) were found to be significantly up related ($p < 0.05$) in athletes with mTBI.⁶⁹ Although candidate miRNA have been identified for TBI, it is critical to acknowledge that larger sample sizes, keeping in consideration of confounding factors such as injury severity, comorbid conditions and age, are needed for more robust and specific outcomes.

3.5 Conclusion and Future Direction

This review describes the evidence about the functions of the glymphatic system during sleep versus wakefulness and defines the implications for AD and TBI research. The structural and biophysiological components of the glymphatic system have brought new understanding to the highly organized transport and clearance system in the brain. The pathway entails a continuous CSF and ISF exchange that is facilitated by AQP4 channels on astrocytic end foot. Additionally, during sleep, the pathway is especially active, with a clearance rate of pathogenic aggregates nearly doubling. A clearer understanding of these underlying mechanisms can aid not only in the identification of individuals at risk

for sleep disorders but may also assist clinicians in providing preventive care for those at increased risk of dysregulated sleep following neurodegeneration and/or brain injury. Additional research is needed to elucidate the details of the human glymphatic system, identify factors that enhance or impair its function and pathological changes in the glymphatic function during human disease development and progression. These innovations could give rise to novel therapeutic targets, such as through biomarker detection, to further improve prognostic and diagnostic tools available in clinical settings. Since the time of ancient Greek philosophers, sleep has been the subject of numerous theories and with the building literature and technology, understanding the glymphatic system may be able to answer some of the fundamental questions of our brain mechanisms.

Figure 7. Glymphatic flow of healthy and injured brain.

The blood brain barrier and blood-CSF separate the CSF and interstitial fluid. The CSF flows into the perivascular space via the astrocytic vascular endfeet expressing AQP4. AQP4 water channels plays a key role in the clearance of pathogenic aggregate protein (e.g. amyloid beta, tau protein) by fluid exchange between the brain parenchyma interstitial fluid and CSF. In the injured brain, astrocytic activation increases AQP4 activation to increase. Additionally, after brain injury there may be increase in pathogenic aggregate proteins around the interstitial that needs to be cleared.

AQP4, aquaporin-4; CSF, cerebrospinal fluid.

Illustration created by Sara Mithani and Erina He from National Institutes of Health Medical Arts

Figure 8. Metabolic clearance during wakefulness and sleep.

During sleep, cerebrospinal fluid (CSF) influx increases two-fold more than wakefulness causing increased metabolic clearance.

Illustration created by Sara Mithani and Erina He from National Institutes of Health Medical Arts

Your Answers for OHSRP Determination '18-NINR-00362' (11/20/2017)

You may [click here](#) to return to OHSRP's Determinations website at any time.

SHOULD I STOP OR GO FORWARD WITH AN OHSRP SUBMISSION?

Question

"If this is a new request (i.e. not an amendment to a previously approved project), have you already started or completed your research activity? (If amending your project select "No" below) "

Your Answer

• No

Question

"Are the specimens/data that will be used in this project coming from an active, NIH IRB-approved protocol; or is the proposed activity a component of an active, NIH IRB-approved protocol, (e.g. the results of this activity will be used in support of the protocol)?"

Your Answer

• No

Question

"Does the NIH investigator or any other collaborator at NIH know the identity of (have identifiers associated with) the living human sources of the specimens/data that will be used on this project? (If the specimens/data are not individually identifiable, but the identity of the subjects may readily be ascertained by the investigator, e.g. because of a small sample size, please answer "Yes" below. Answer "No" below if interacting with subjects to conduct survey, interview or focus group research. Answer "No" below if conducting a retrospective chart review and will have no way to link the data to identifiers after completion)."

Your Answer

• No

Question

"Does this activity involve prisoners?"

Your Answer

• No

Question

"For this project, is NIH conducting a research activity that is part of an FDA-regulated protocol approved by an IRB, e.g. the protocol is studying the safety or efficacy of unapproved drugs/devices or new uses of approved drugs/devices?"

Your Answer

• No

Question

"* If yes, has the collaborator confirmed that the planned research activity, which will occur at NIH, is included in the IRB/ethics committee-approved protocol and consent form at his/her institution?"

Your Answer

** DID NOT ANSWER **

SECTION I - GENERAL INFORMATION

Question

"Project Title:"

Your Answer

RNA Expression and Insomnia

Question

"Project Description:"

Your Answer

We will examine the gene expression of participants with insomnia compared to participants classified as good sleepers. Samples will be analyzed from 30 subjects enrolled in the Metabolomics of Insomnia-Related Hyperarousal Study at the University of Pennsylvania, who have contributed blood samples for RNA sequencing analysis. The purpose of this study is to compare patterns of gene expression between people with insomnia versus good sleepers.

Question

"Upload Additional Project Information or Narrative Template (More Information):"

Your Answer

** DID NOT ANSWER **

Question

"Proposed Start Date:"

Your Answer

12/18/2017

Question

"Proposed Completion Date:"

Your Answer

12/18/2020

Question

"Search for Requestor (your name):"

Your Answer

Cassandra Lee Pattinson

Question

"If you are not the Senior Investigator (SI), what is your role?"

Your Answer

• Other, specify:

Question

"Other - please enter additional information here"

Your Answer

Post-doctoral visiting fellow who will oversee the study

Question

"Search for Senior Investigator*:"

Your Answer

Jessica M Gill

Question

"Search for Supervisor**:"

Your Answer

Ann King Cashion

Question

"Are there any additional NIH Investigators on your team conducting this research (e.g. junior investigator, contractor, fellow, student, etc...)?"

Your Answer

- Yes
-

Question

"Search for Additional Investigator #1:"

Your Answer

Chen Lai

Question

"Search for Additional Investigator #2:"

Your Answer

Hyung Suk Bruce Kim

Question

"Search for Additional Investigator #3:"

Your Answer

** DID NOT ANSWER **

Question

"Search for Additional Investigator #4:"

Your Answer

** DID NOT ANSWER **

Question

"Search for Additional Investigator #5:"

Your Answer

** DID NOT ANSWER **

SECTION II - SPECIAL CATEGORIES

Question

"Only select the applicable activities or materials below, if they are involved in the project. PLEASE NOTE: The majority of projects do not involve any of the activities listed below. Simply select "Involves other types of specimens/data or research activities" unless you are sure your activities are listed below. (Select all that apply.)"

Your Answer

** DID NOT ANSWER **

Question

"I (the Senior Investigator) certify that the proposed project:"

Your Answer

- Involves other types of specimens/data or research activities than those listed above. Please continue completing the request for determination form.

SECTION III - COLLABORATORS AND OTHER ENTITIES

Question

"Collaborator #1:"

Your Answer

Philip Gehrman

Question

"Institution/IC Name:"

Your Answer

University of Pennsylvania

Question

"FWA #:"

Your Answer

FWA00004028

Question

"City/State/Country:"

Your Answer

Philadelphia, PA

Question

"Email Address:"

Your Answer

gehrman@upenn.edu

Question

"Collaborator Actions"

Your Answer

• Both

Question

"Additional Collaborator Details:"

Your Answer

Dr. Gehrman is an assistant professor of psychology in the Department of Psychiatry at the University of Pennsylvania and will aid in obtaining samples and related clinical and demographic data. He will also be involved in reviewing the data generated.

Question

"Collaborator #2:"

Your Answer

Lai Chen

SECTION III - COLLABORATORS AND OTHER ENTITIES

Question

"Collaborator #1:"

Your Answer

Philip Gehrman

Question

"Institution/IC Name:"

Your Answer

University of Pennsylvania

Question

"FWA #:"

Your Answer

FWA00004028

Question

"City/State/Country:"

Your Answer

Philadelphia, PA

Question

"Email Address:"

Your Answer

gehrman@upenn.edu

Question

"Collaborator Actions"

Your Answer

• Both

Question

"Additional Collaborator Details:"

Your Answer

Dr. Gehrman is an assistant professor of psychology in the Department of Psychiatry at the University of Pennsylvania and will aid in obtaining samples and related clinical and demographic data. He will also be involved in reviewing the data generated.

Question

"Collaborator #2:"

Your Answer

Lai Chen

"FWA #:"

Your Answer

FWA00005897

Question

"City/State/Country:"

Your Answer

Bethesda, MD

Question

"Email Address:"

Your Answer

kimhy@mail.nih.gov

Question

"Collaborator Actions"

Your Answer

• Both

Question

"Additional Collaborator Details:"

Your Answer

Samples will also be analyzed under the supervision of Dr. Kim.

Question

"Upload Additional Collaborator Information:"

Your Answer

** DID NOT ANSWER **

SECTION IV - RESEARCH WITH SPECIMENS AND DATA

Question

"Does this activity include any of the following? (Select all that apply)"

Your Answer

- Research with specimens and/or data
-

Question

"Other - please enter additional information"

Your Answer

** DID NOT ANSWER **

Question

"* If you selected Program Evaluation or QA/QI above, does the activity only involve interview or survey procedures?"

Your Answer

** DID NOT ANSWER **

Question

"What role(s) will the NIH Investigator(s) have on this research project? (Select all that apply)"

Your Answer

- Receiving data/specimens from a collaborator to conduct research
 - Analyzing specimens or data
 - Running laboratory assays for research
 - Sending data/specimens to a collaborator to conduct research
-

Question

"Other - please enter additional information here"

Your Answer

** DID NOT ANSWER **

Question

"Identify the types of data or specimen involved in this project (Select all that apply)"

Your Answer

- Specimens, specify below:
-

Question

"Medical Records - specify source"

Your Answer

** DID NOT ANSWER **

Question

"Data - specify type"

Your Answer

**** DID NOT ANSWER ****

Question

"Specimens - specify type"

Your Answer

whole blood

Question

"Imaging - specify type"

Your Answer

**** DID NOT ANSWER ****

Question

"Other - please enter additional information here"

Your Answer

**** DID NOT ANSWER ****

Question

"Biorepository - specify name"

Your Answer

**** DID NOT ANSWER ****

Question

"Database or website - Enter name and URL"

Your Answer

**** DID NOT ANSWER ****

Question

"Select attachment to upload:"

Your Answer

De-Identification_Agreement_Template_Gill_and_Gehrman.pdf

SECTION IV - RESEARCH WITH SPECIMENS AND DATA - Continued

Question

"Do all the specimens/data or information already exist?"

Your Answer

- Yes
-

Question

"If Yes, were the specimens/data for this project originally collected for:"

Your Answer

- research purposes (even if also collected for clinical purposes)
-

Question

"Is/was there IRB/Ethics Committee approval for the collection or use of the specimens/data at your collaborator's site (if applicable)?"

Your Answer

- Yes
-

Question

"Please select the response that best describes the specimens/data utilized for this activity: (Please confirm this with your collaborator, if applicable, prior to submitting this form.)"

Your Answer

- Specimens/data will be coded, however that code cannot be used by anyone to identify specific individuals.
-

Question

"If an existing identifiable specimens/data set will be de-identified before the research commences, please indicate who will conduct the de-identification:"

Your Answer

- Collaborator(s) or provider(s) of the specimens/data
-

Question

"NIH SENIOR INVESTIGATOR CERTIFICATION FOR RESEARCH INVOLVING CODED SPECIMENS/DATA Answer below only when the other party can identify the human source(s) directly, through a code-key or when using an Honest Broker:

I (the Senior Investigator) certify that I will not be able to re-identify the human source(s) of the specimens/data in this project, and I have obtained one or more of the following to confirm this. Further, I promise to retain this documentation and provide it upon request. (Select all that apply)"

Your Answer

- An email confirmation between the collaborator and the NIH investigator that contains the de-identification agreement (Click [here](#) to read the OHRP regulatory guidance and click [here](#) to download the De-identification Agreement Email Template)
-

Question

"If applicable, will the recipient of the specimens/data be returning results to the sender? (Select all that apply)"

Your Answer

- Yes, only aggregate results will be returned (e.g. summary statistics, not individual line-item data)
-

Question

"* If coded results are being returned to a collaborator who has the code-key to re-identify the human sources of the specimens/data, is there IRB/ethics committee approval for this research collaboration at the collaborator's institution?"

Your Answer

** DID NOT ANSWER **

Question

"Additional Info:"

Your Answer

** DID NOT ANSWER **

**SECTION V - RESEARCH INVOLVING EDUCATIONAL RESEARCH OR TESTING, SURVEY OR
INTERVIEW PROCEDURES, OR OBSERVATION OF PUBLIC BEHAVIOR**

Question

"Specify the types of research or procedures involved in this project: (Select all that apply)"

Your Answer

** DID NOT ANSWER **

Question

"Other - please enter additional information here"

Your Answer

** DID NOT ANSWER **

Question

"How will data collection be conducted? (Select all that apply)"

Your Answer

Case Western Reserve University	BSN	Nursing	2009

EDUCATION IN PROGRESS

<u>Institution</u>	<u>Degree</u>	<u>Major</u>	<u>Year</u>
University of Illinois Chicago	PhD	Nursing	Expected 05/2020

ADDITIONAL TRAINING

2019	Certificate in Sleep Health; University of Illinois at Chicago, Chicago IL
2019	Applied Machine Learning; 1 semester course at National Institutes of Health; Grade: A
2019	Introduction to Python; 1 semester course at National Institutes of Health; Audit
2019	SciPhD Certificate Program: The Business of Science; National Institutes of Health
2019	Translational Science Training Program; 2-day intensive at National Institutes of Health
2019	Bioinformatic for Analysis of Next Generation Sequencing; 1 semester course at National Institutes of Health; Audit
2018	Summer Genetics Institute; 4-week intensive at National Institutes of Health
2017	Graduate Summer Opportunity to Advance Research; 3 month summer fellowship at National Institutes of Health with focus on translational research

EMPLOYMENT AND TEACHING

2016-2019	Maxim Healthcare Registered Nurse, Chicago, Illinois
2016-2019	Research Assistant, Laboratory of Sleep Neurobiology, Chicago, Illinois Lab Principal Investigator- Dr. Anne Fink
2017-2018	Teaching Assistant; NURS 534: Advanced Physiology
2016-2017	Teaching Assistant; NURS 397: Issues in Nursing Practice
2014-2016	Research Assistant, Neuroscience Laboratory, Cleveland, Ohio Lab Principal Investigator- Dr. Michael Decker
2012-2014	Research Assistant, Heart ABC-Adherence, Behavior, Cognition Study Principal Investigator- Dr. Mary Dolansky

HONORS AND AWARDS

2020	Scholarship and Acceptance to attend American Academy of Sleep Medicine Foundation Young Investigators Research Forum
2020	Podium Presentation at National Institutes of Health Graduate Symposia
2019-2020	Graduate Partnership Program at the National Institutes of Health- National Institutes of Nursing Research

2018-2020	Jonas Healthcare Scholar, 2018-2020 Cohort
2019	Invited International Presentation at Aga Khan University, Karachi, Pakistan. "From Bedside to Bench: The Future of Nursing Science"
2018-2019	W. E. Van Doren Scholarship
2017	University of Illinois College of Nursing Travel Funding for Midwest Nursing Research Society
2018	Kappa Alpha Theta Foundation Scholarship
2016-2018	Ph.D. Deans Teaching Assistant Award
2016	Case Western Reserve University School of Nursing Travel Funding for Midwest Nursing Research Society
2015	2 nd Place Poster Presentation Award, Case Western Reserve University Research Symposium
2015	Summer Research Program Funding Recipient (\$3,500)
2015-2016	Deans High Honors- Case Western Reserve University
2015-2016	Outstanding Campus Partner, Spartans for Special Olympics
2014-2015	Dorothy Pijan Outstanding Establishment Student Event, Spartans for Special Olympics
2014	2 nd Place Poster Presentation Award, Case Western Reserve University Research Symposium
